

Shallow Water Hydroids from Eastern Bass Strait

Jeanette E. Watson*

Introduction

Previous records of hydroids from Bass Strait east of Wilsons Promontory include four species collected by the *Challenger* Expedition (1873-76) from a depth of 70 m off Moncoeur Island (Allman 1888) and four species from the *Endeavour* trawlings in 146-546 m on the eastern slope (Bale 1915). Five species from a depth of 82 m, described by Busk (1852) from the voyage of the *Rattlesnake*, may have been dredged in Banks Strait, off the north-eastern coast of Tasmania.

Until 1915, only three species *Sertularia unguiculata* (Busk 1852), *Stereothecha elongata* (Lamouroux 1816) and *Amphisbetia operculata* (Linnaeus 1758) were recorded from depths of less than 60 m in eastern Bass Strait, the first two from Banks Strait (Busk 1852), *S. unguiculata* from Sealers Cove on the eastern side of Wilsons Promontory (Bale 1884) and *A. operculata* from near Devonport (Bale 1915). The few eastern Victorian shallow water records from previous Australian researchers (e.g. Bale, Spencer, Bartlett, Mulder and Trebilcock) probably reflects the inaccessibility of much of this part of the coastline to earlier workers.

This paper lists hydroids recorded to depths of 60 m in eastern Bass Strait. Most of the material was collected by the author, using SCUBA. The list includes collections from the Kent Group (1974 and 1993) (KGI), from shallow reefs off the Ninety Mile Beach (Woodside Beach to Delray Beach, 1977-1992) (NMB), from Gabo Island; Iron Prince reef and Mallacoota in the east (1973-1975) (GBI), from the Halibut and Marlin oil production platforms in central eastern Bass Strait (1974) (HMP), from the Seal Islands Group and the Nooramunga Reserve near Wilsons Promontory (1983-1992) (NOR) and near Flinders Island (FLI). Localities are shown in Fig. 1.

The list includes 9 species of athecate hydroids and 73 species of thecate hydroids. No doubtful or undescribed species are listed nor has any taxonomic revision been attempted in this paper. Species are listed with locality, depth range of collection and substrate notes where available. These provide an indication of the bathymetric range and habitat preferences of each species.

Ecological notes

While all but one of the records are from the sublittoral zone, some of the epiphytic species listed may be expected to also occur on algae in tide pools on rocky shores in far eastern Victoria. The list gives no indication of the abundance or rarity of species; for example, the very small species, *Calamphora parvula* recorded for the first time from Bass Strait since its original description (Allman 1888), is rare, whereas the large plumose species, *Aglaophenia divaricata*, is very common on coastal reefs.

Some species, for example *Obelia geniculata*, *Silicularia rosea*, *Orthopyxis caliculata* and *Aglaophenia setaceoides*

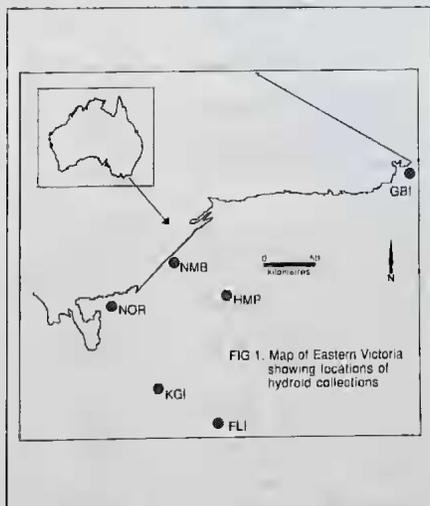

Fig. 1. Map of eastern Victorian showing locations of hydroid collections.

* Honorary Associate, Museum of Victoria
285 Russell Street Melbourne 3000.

are epiphytes on brown algae, the most important associations being with *Phyllospora comosa*, *Ecklonia radiata* and *Sargassum* spp. Other species such as *Aglaophenia plumosa*, *Halecium delicatulum* and *Halopteris campanula* are epizooites on other invertebrates including bryozoans, many species of sponges and the solitary ascidians *Herdmania momus* (Savigny), *Pyura australis* (Quoy and Gaimard) and *Pyura stolonifera* (Heller). Larger forms including *Aglaophenia divaricata*, *Aglaophenia whiteleggei* and *Gyunaugium superbium*, while listed as epilithic, frequently grow from a rootstock directly attached to rocky substrate. Their larvae may, however, have originally settled on small invertebrates on the rock surface. *Nemertesia watsi* and *Amphisbetia operculata* are usually not associated with reefs and often form large colonies growing on fragments of shell and rubble in open waters, especially in places of strong current flow. *Clytia hemisphaerica*, a small opportunis-

tie species, favours many different substrates, and rich colonies may grow on artificial surfaces such as buoys or raft on fragments of the seagrass *Heterozostera tasmanica* drifting in ocean currents.

Size, habit and colour are all characteristics useful for recognition of hydroids to generic, and often to specific level. Most epiphytes are stolonial, the colonies usually growing close to the algal thallus; in general these species tend to be white in colour, or almost colourless. Erect-growing species, irrespective of habit, are often brightly coloured. *Aglaophenia divaricata* forms dense brown to black feathery colonies which may grow to 20 cm high while a similar species, *Lytocarpus whiteleggei*, is white. *Halopteris caupanula* is lax in habit and bright orange in colour; *Sertularia macrocarpa* forms large colonies that are silvery white *in situ* but appear black out of the water. Most species of *Gyunaugium* have tall plumose stems that vary from green to brown in colour.

Table 1. Hydroid species recorded from depths of 0-60 m from eastern Bass Strait.

Species	Locality	Depth, m	Substrate notes
ATHECATA			
Family Hydractiniidae			
<i>Sylactis betkensis</i> Watson, 1978	GBI	0-1	on gastropod <i>Parcanassa burghardi</i>
Family Coryniidae			
<i>Sarsia radiata</i> Lendenfeld, 1884	NMB HMP	3-10	buoy lines and mussels (<i>Mytilus planulatus</i>)

***The Victorian Naturalist* - Back Issues**

Complete volumes are available, from Volume 63 up to the present. Back numbers start from Volume 11, but some issues are missing. Prices are those given below, plus postage.

Per Part, vols. up to 91 - 50 cents minimum.

Per Part, vols. up to 92 - 75 cents.

Per Part, vols. 93 to 95 - \$1.20, vols. 101 to 102 - \$2.50.

Per Part, vols. 96 to 99 - \$1.75, vols. 103 to 104 - \$3.00.

Per Part, vol. 100 - \$2.20, vols. 105 to 106 - \$3.50.

Volumes up to Vol. 91 contain 12 parts per volume, Vol. 92 has 11 parts and volumes 93 onwards have 6 parts.
